PERNYATAAN

Dengan ini saya yang bertandatangan di bawah ini menyatakan bahwa contoh skripsi dengan judul:

INTEGRASI SITUS NAVIGASI DENGAN SITUS *CROWDSOURCING* RUTE ANGKOT

adalah benar-benar karya saya sendiri, dan saya tidak melakukan penjiplakan atau pengutipan dengan cara-cara yang tidak sesuai dengan etika keilmuan yang berlaku dalam masyarakat keilmuan.

Atas pernyataan ini, saya siap menanggung segala risiko dan sanksi yang dijatuhkan kepada saya, apabila di kemudian hari ditemukan adanya pelanggaran terhadap etika keilmuan dalam karya saya, atau jika ada tuntutan formal atau non-formal dari pihak lain berkaitan dengan keaslian karya saya ini.

Dinyatakan di Bandung,
Tanggal 19 Maret 2015

ABSTRAK

Penelitian ini mengintegrasikan situs navigasi rute angkot http://kiri.travel dengan situs *crowdsourcing* rute angkot https://angkot.web.id, di mana pengguna dapat berkontribusi memperbaiki rute angkot yang salah. Integrasi yang dimaksud adalah sinkronisasi data secara berkala dan otomatis, sehingga hasil navigasi yang diberikan mendekati ketepatan sesuai di lapangan.

TODO Sisa abstrak akan dilengkapi saat penelitian berakhir.

Kata-kata kunci: *crowdsourcing*, angkot, rute, navigasi, *REST*, *JSON*

ABSTRACT

This research integrates *angkot* (public bus) navigation website http://kiri.travel with *angkot* route crowdsourcing website, where public user can contribute by fixing erroneus *angkot* routes. The aforementioned integration is defined as automatic synchronization of both parties' data, such that the result accuracy of navigation is close to what found on the field.

TODO The rest of abstract will be completed at end of research.

Keywords: crowdsourcing, route, navigation, REST, JSON

Dipersembahkan untuk seluruh warga Indonesia yang selalu setia menggunakan transportasi umum dan mahasiswa FTIS UNPAR yang akan menyelesaikan skripsinya.

BAB 1

PENDAHULUAN

1.1 Latar Belakang

KIRI (http://kiri.travel) adalah sebuah situs yang dikelola oleh PT. Kirana Sistem Transportasi, yang menyediakan layanan navigasi dari satu titik ke titik lain memanfaatkan transportasi publik. Layanan ini diberikan secara gratis kepada pengunjung situs / pengguna aplikasi bergerak mereka. Untuk mendukung layanan tersebut, tim KIRI melakukan kurasi rute angkot secara mandiri di Bandung dengan mencatat perjalanan setiap trayek menggunakan peralatan GPS (*Global Positioning System*). Pada perkembangannya, KIRI melakukan ekspansi ke beberapa kota lainnya termasuk Jakarta. Hanya saja, karena keterbatasan sumberdaya data di Jakarta dimasukkan berbekal data yang tersedia di internet, tanpa validasi di lapangan. Di sisi lain, ada beberapa pihak yang tertarik akan layanan KIRI di Bandung dan berniat untuk mendapatkan layanan serupa di kota mereka. Tampilan situs web KIRI dapat dilihat pada gambar 1.1.

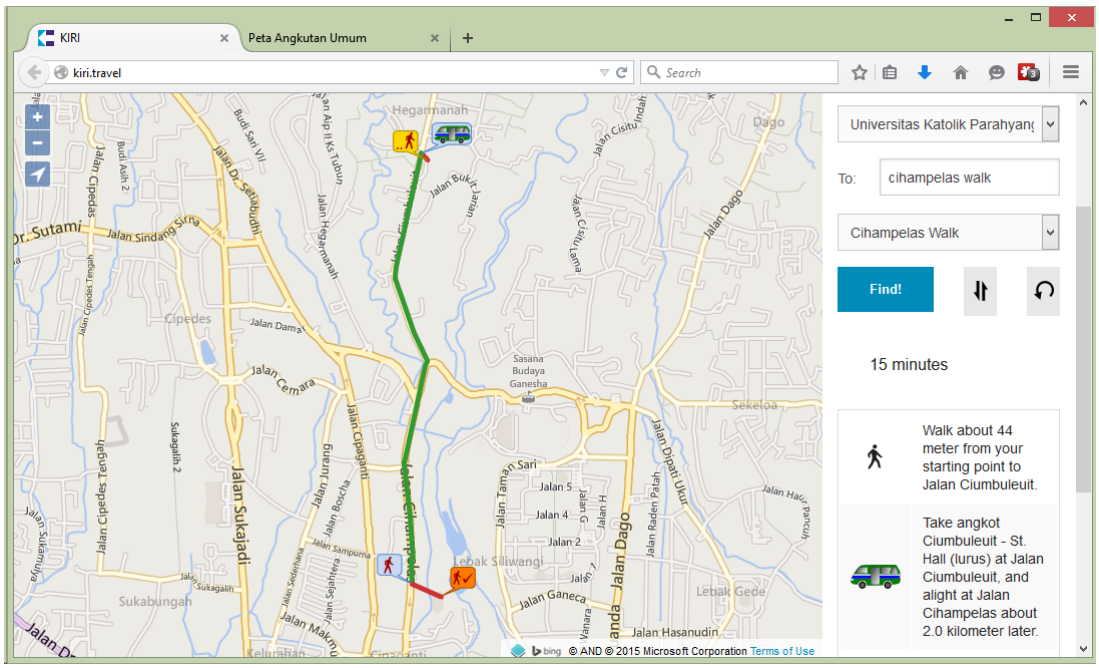
Situs https://angkot.web.id (selanjutnya disebut angkot.web.id saja) merupakan sebuah situs yang dikembangkan oleh Fajran Iman Rusadi yang berbasis di Belanda. Situs ini memungkinkan pengguna publik untuk melihat, memasukkan, atau memperbaiki data rute angkot di Indonesia (dengan kata lain, *crowdsourcing*). Layanan ini juga diberikan secara gratis. Tampilan situs web angkot.web.id dapat dilihat pada gambar 1.2

Sampai saat ini, KIRI serta angkot.web.id merupakan dua buah situs yang terpisah dan bekerja secara independen.

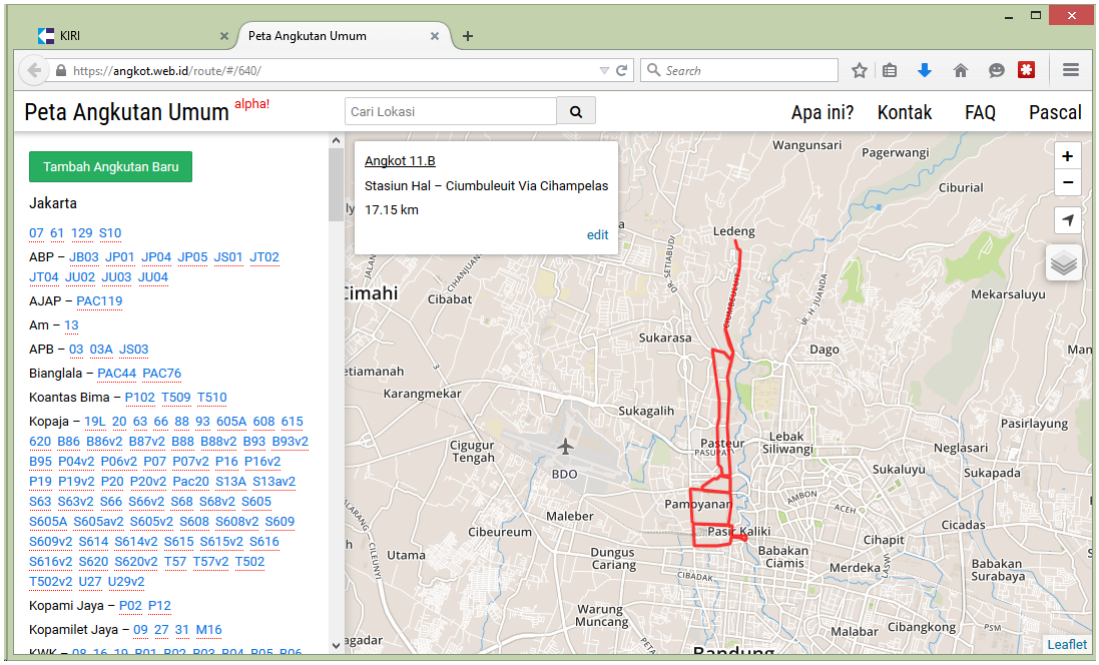
1.2 Rumusan Masalah

Dari latar belakang yang sudah dijelaskan, peneliti bermaksud untuk mengintegrasikan data yang dimiliki kedua situs web tersebut. Integrasi tersebut dirumuskan ke dalam masalah-masalah berikut:

- Bagaimana mekanisme penarikan data oleh KIRI terhadap angkot.web.id secara otomatis?
- Bagaimana memisahkan data yang dimiliki oleh KIRI sendiri dengan data yang ditarik dari angkot.web.id?
- Bagaimana mengoptimasi protokol yang digunakan, sehingga kebutuhan *bandwidth* dapat dihemat?
- Bagaimana respon pengguna KIRI terhadap fitur yang diimplementasikan?



Gambar 1.1: Situs Web KIRI



Gambar 1.2: Situs angkot.web.id

1.3 Tujuan

Berdasarkan rumusan masalah yang sudah dijabarkan, maka didefinisikan tujuan-tujuan berikut:

- Mengimplementasikan mekanisme penarikan data otomatis oleh KIRI terhadap angkot.web.id.
- Mengimplementasikan pemisahan data antara rute milik KIRI dengan data yang ditarik dari angkot.web.id.
- Mengoptimasi protokol yang digunakan, sehingga kebutuhan *bandwidth* dapat dihemat.
- Mempelajari respon pengguna KIRI terhadap fitur yang diimplementasikan.

1.4 Batasan Masalah

Penelitian ini memiliki batasan-batasan seperti berikut:

- Penelitian dilakukan untuk rute angkot kota Bandung saja.
- Integrasi otomatis akan dilakukan secara berkala (tidak *realtime*).
- Dengan alasan kerahasiaan, mesin navigasi KIRI dan angkot.web.id hanya dijelaskan pada bagian-bagian yang terkait dengan penelitian ini saja.

1.5 Metode Penelitian

Dalam penelitian ini, akan dilakukan langkah-langkah berikut:

- Melakukan studi terhadap mesin navigasi KIRI, protokol angkot.web.id, serta teori-teori lain yang mendukung kedua hal tersebut.
- Melakukan analisis untuk menemukan hal yang dapat dilakukan untuk mengintegrasikan data kedua situs tersebut.
- Melakukan perancangan untuk implementasi integrasi kedua sistem tersebut.
- Melakukan implementasi dari rancangan yang sudah dilakukan.
- Melakukan publikasi terhadap pengguna KIRI sehingga mereka dapat menguji hasil implementasi tersebut.
- Menarik kesimpulan atas hasil yang telah dilaksanakan.

1.6 Sistematika Penulisan

Berikut adalah sistematika penulisan dari dokumen ini:

- Bab 1 membahas latar belakang, rumusan masalah, tujuan penulisan, batasan-batasan, serta metode yang digunakan pada penelitian ini.

- Bab 2 membahas teori-teori yang digunakan dalam penelitian ini.
- Bab 3 membahas analisis yang dilakukan terhadap teori yang telah dijabarkan pada bab 2.
- Bab 4 membahas perancangan yang dilakukan sebelum mengimplementasikan integrasi yang dimaksud.
- Bab 5 membahas implementasi serta pengujian dari integrasi yang telah dilakukan.
- Bab 6 membahas kesimpulan dari keseluruhan penelitian ini, serta saran-saran yang dapat diberikan untuk penelitian berikutnya.

BAB 2

LANDASAN TEORI

2.1 Mesin Navigasi KIRI

KIRI memiliki mesin navigasi yang dibangun pada bahasa Java. Mesin ini bertugas untuk menerima masukan berupa koordinat titik asal dan tujuan, kemudian menemukan angkot-angkot yang harus dinaiki untuk menuju titik tujuan dari titik asal. Karena alasan kerahasiaan, pembahasan mengenai mesin navigasi KIRI tidak mengacu pada referensi publik, melainkan dari survei terhadap kode sumber internal KIRI.

Seperti dapat dilihat pada gambar 2.1, elemen arsitektur yang mendukung navigasi KIRI dibagi menjadi tiga, yaitu:

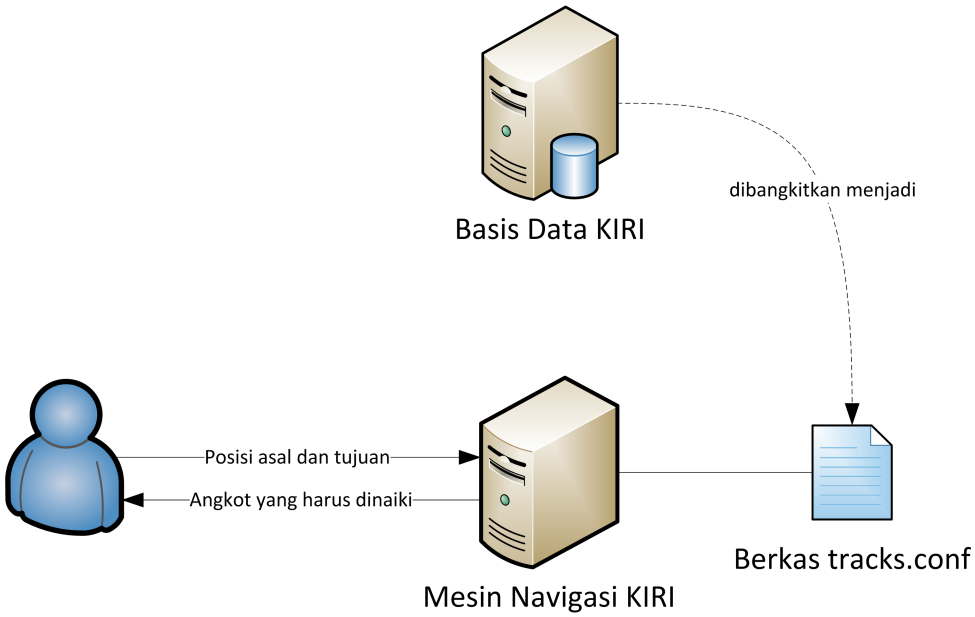
Basis Data KIRI menyimpan informasi rute 33 trayek angkot, yang masing-masing mencakup identifikasi trayek (`trackId` dan `trackTypeId`), nama trayek (`trackName`), daftar koordinat yang dilewati (`geodata`), informasi pulang-pergi (`pathloop`), catatan internal (`internalInfo`), prioritas untuk dipilih (`penalty`), informasi naik/turun penumpang (`transferNodes`), dan parameter ekstra untuk pembelian tiket (`extraParameters`).

Berkas tracks.conf adalah hasil ekstraksi dari basis data KIRI, yang menyimpan informasi penting saja yang dibutuhkan oleh algoritma mesin navigasi KIRI, yakni: `trackId`, `trackTypeId`, `penalty`, `geodata`, `pathloop`, dan `transferNodes`.

Mesin Navigasi KIRI adalah program yang bertugas mengolah data yang ada pada berkas tracks.conf, sehingga dapat menjawab pertanyaan navigasi dari titik asal ke titik tujuan. Karena alasan historis, mesin navigasi tidak membaca data langsung dari basis data, melainkan dari berkas tracks.conf.

2.1.1 Basis Data KIRI

Basis data KIRI disimpan dalam sistem manajemen basis data MySQL. Salah satu dari tabel yang digunakan adalah tabel `tracks`, yang menyimpan informasi rute trayek. Struktur dari tabel ini dijelaskan pada tabel 2.1.



Gambar 2.1: Arsitektur Saat Ini

Tabel 2.1: Struktur Tabel tracks

Nama kolom	Tipe	Keterangan
trackId	varchar(32)	Kode trayek angkot (misal: "sthallciumbuleuitlurus"). Menjadi PRIMARY KEY tabel bersama trackTypeId.
trackTypeId	varchar(32)	Kode tipe trayek (untuk angkot bandung, selalu berisi "bdo_angkot"). Menjadi PRIMARY KEY bersama trackId.
trackName	varchar(32)	Nama trayek yang dapat dibaca secara umum (misal: "St. Hall - Ciumbuleuit (lurus)").
internalInfo	varchar(1024)	Informasi internal yang dapat ditambahkan dan tidak akan ditampilkan pada hasil pencarian.
geodata	linestring	Daftar koordinat dari rute trayek ini.
pathloop	tinyint(1)	Menandakan apakah trayek ini adalah trayek pulang pergi atau satu arah.
penalty	decimal(4,2)	Bobot dari trayek ini. Semakin besar nilainya, semakin kecil kemungkinan akan muncul pada hasil navigasi.
transferNodes	varchar(1024)	Daftar indeks titik di mana penumpang dapat turun maupun naik, dipisahkan dengan koma. Untuk angkot Bandung, penumpang dapat turun dan naik di semua titik.
extraParameters	varchar(256)	Informasi yang ditambahkan saat melakukan pembelian tiket (tidak terkait dengan penelitian ini).

2.1.2 Berkas tracks.conf

Karena alasan historis[1], mesin navigasi KIRI tidak mengakses langsung ke basis data MySQL, melainkan membaca sebuah berkas yang bernama `tracks.conf`.

Berkas `tracks.conf` ini merupakan sebuah berkas teks yang menyimpan basis data trayek yang telah dibersihkan untuk dapat dibaca dengan mudah, satu *record* per baris. Setiap baris berisi 6 *field* yang dipisahkan dengan *tab* (`\t`). Berikut adalah penjelasan dari keenam *field* tersebut:

trackTypeId.trackId Berisi `trackTypeId` dan `trackId` dipisahkan dengan titik.

penalty Berisi nilai `penalty`.

numberOfNodes Berisi jumlah *node* (titik) dari rute trayek ini.

nodes Berisi daftar koordinat *node* dari rute trayek ini dipisahkan dengan *tab*. Setiap koordinat node terdiri dari *latitude* dan *longitude* yang dipisahkan dengan spasi.

pathLoop Berisi nilai `pathloop` yang menunjukkan apakah rute ini merupakan rute pulang pergi atau searah.

transferNodes Berisi nilai `transferNodes` yang menunjukkan titik-titik di mana penumpang diperbolehkan untuk naik / turun.

2.1.3 Mesin Navigasi KIRI

Mesin navigasi KIRI merupakan sebuah program yang mendengarkan dan menjawab permintaan navigasi dalam bentuk *HTTP request* di *port* 8000. Program ini dibangun di atas bahasa Java, yang terdiri dari beberapa kelas yang ditunjukkan pada gambar 2.2.

Adapun penjelasan untuk setiap kelas dapat dilihat di bawah ini:

Main Kelas yang berfungsi sebagai antarmuka program, untuk dijalankan dari *console*.

NewMenjanganServer Kelas yang bertugas menjalankan program sebagai server, yakni menyiapkan servis-servis untuk dijalankan.

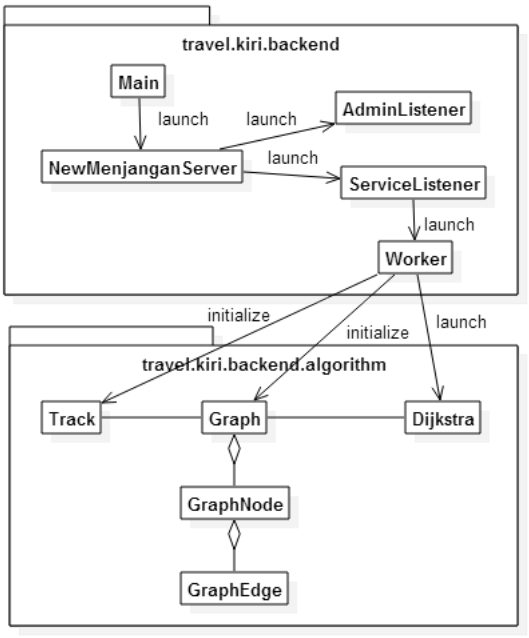
AdminListener Kelas yang berfungsi untuk mendengarkan dan merespon perintah administrasi, seperti *ping*, *shutdown*, dll.

ServiceListener Kelas yang berfungsi untuk mendengarkan dan merespon permintaan untuk navigasi. Servis ini menerima masukan berupa koordinat asal dan tujuan, dan mengembalikan rute angkot yang harus dinaiki.

Worker Kelas ini berfungsi untuk melakukan pekerjaan yang telah diterima oleh ServiceListener. Selain itu, di awal kelas ini juga menyiapkan bahan-bahan yang diperlukan untuk melakukan perhitungan rute, yakni mengkonversi data trayek ke dalam bentuk graf.

Track Kelas ini berfungsi untuk menyimpan informasi sebuah trayek angkot beserta rutenya.

[1] Pada awalnya mesin navigasi KIRI dibangun menggunakan bahasa C++, sehingga menyulitkan dalam mengakses basis data MySQL



Gambar 2.2: Diagram Kelas Sistem Kini

Graph Kelas ini merepresentasikan sebuah graf.

GraphNode Kelas ini merepresentasikan setiap *node* yang dimiliki oleh graf.

GraphEdge Kelas ini merepresentasikan sebuah *edge* dari GraphNode.

Dijkstra Kelas ini merepresentasikan algoritma *Dijkstra's shortest path*[3], untuk digunakan dalam pencarian rute.

2.2 Protokol angkot.web.id

Berdasarkan kode sumber angkot.web.id [4], situs angkot.web.id memanfaatkan *HTTP request* [5] untuk menerima perintah-perintah dan mengembalikan respon berupa data dalam sintaks JSON [6]. Beberapa dari perintah tersebut dijelaskan pada subbab-subbab berikut.

2.2.1 Transportation List

Perintah ini digunakan untuk mendapatkan daftar semua daftar transportasi umum, dan dapat diakses pada dengan melakukan *HTTP request GET* pada path `/route/transportation-list.json`, tanpa parameter apapun. Adapun kembalian dari perintah ini adalah:

- `status`: Status kembalian dari perintah yang dikirimkan
- `provinces`: *Array* provinsi yang terdaftar, masing-masing elemen merupakan *array* lain yang berisi:
  - Kode provinsi
  - Nama provinsi

- `transportations`: *Array* provinsi yang terdaftar, masing-masing berisi:
  - `hasroute`: Menyatakan apakah trayek ini memiliki data rute
  - `company`: Perusahaan pengelola trayek ini
  - `id`: Indeks trayek ini dalam basis data
  - `origin`: Awal rute trayek
  - `destination`: Akhir rute trayek
  - `province`: Provinsi tempat trayek ini beroperasi
  - `city`: Kota tempat trayek ini beroperasi
  - `number`: Nomer trayek
  - `created`: *UNIX time* trayek ini dibuat
  - `updated`: *UNIX time* trayek ini terakhir diperbaharui

Contoh kembalian dari perintah transportation list dapat dilihat pada kode di bawah ini:

```
{
    "status": "ok",
    "provinces": [
        [
            "ID-AC",
            "Aceh"
        ],
        ...
    ],
    "transportations": [
        {
            "hasRoute": true,
            "company": "KWK",
            "id": 21,
            "origin": null,
            "destination": null,
            "province": "ID-JK",
            "city": "Jakarta",
            "number": "S15A",
            "created": "1379952348",
            "updated": "1379952379"
        },
        ...
    ]
}
```

2.2.2 Transportation Detail

Perintah ini digunakan untuk mendapatkan detail dari sebuah trayek transportasi, dan diakses dengan melakukan *HTTP request GET* pada path `/route/transportation/nnn.json` (di mana *nnn* adalah nomer kode trayek dalam basis data). Adapun kembalian dari perintah ini adalah:

- `id`: Nomer kode trayek.
- `geojson`: Data rute dan atributnya dalam format GeoJSON[7], terdiri dari:
  - `type`: Tipe GeoJSON yang digunakan
  - `properties`: Properti-properti data GeoJSON, terdiri dari:
    - `number`: Nomer trayek
    - `accept`: *tidak diketahui*

        * `company`: Perusahaan pengelola trayek ini
        * `destination`: Akhir rute trayek
        * `province`: Provisi tempat trayek ini beroperasi
        * `origin`: Awal rute trayek
        * `city`: Kote tempat trayek ini beroperasi
      - `properties`: Data geometri rute trayek ini, mengikuti standar GeoJSON untuk tipe data `MultiLineString`.

- `created`: *UNIX time* trayek ini dibuat
- `status`: Status kembalian dari perintah yang dikirimkan
- `submission_id`: Kode submisi dari trayek yang dimaksud
- `updated`: *UNIX time* trayek ini terakhir diperbaharui

Contoh kembalian dari perintah transportation dapat dilihat pada kode berikut:

```
{
    "id": 348,
    "geojson": {
        "type": "Feature",
        "properties": {
            "number": "M24v2",
            "accept": [],
            "company": "Mikrolet",
            "destination": "Joglo",
            "province": "ID-JK",
            "origin": "Terminal Grogol",
            "city": "Jakarta"
        },
        "geometry": {
            "type": "MultiLineString",
            "coordinates": [
                [
                    [106.79068207740782, -6.166144969433212],
                    [106.79347157478333, -6.166107635752627],
                    [106.79707646369934, -6.165899633769797],
                    ...
                ],
                [
                    [106.7961323261261, -6.196021736671819],
                    [106.7957353591919, -6.196037735916297],
                    [106.79550468921661, -6.195936407359816],
                    ...
                ]
            ]
        }
    },
    "created": "1402504737",
    "status": "ok",
    "submission_id": "CaZVRi",
    "updated": "1402506397"
}
```

BAB 3

ANALISIS

3.1 Mesin Navigasi KIRI

3.1.1 Mekanisme Penarikan

Untuk mendukung integrasi data antara angkot.web.id dan KIRI, diperlukan adanya penarikan secara berkala terhadap angkot.web.id oleh KIRI. Ada dua alternatif metode yang dipertimbangkan sebagai mekanisme penarikan data ini:

Metode *realtime* Metode ini mendeteksi setiap perubahan yang terjadi pada data angkot.web.id, dan langsung memberi notifikasi kepada KIRI untuk mengambil ulang data yang berubah dari angkot.web.id

Metode *polling* Pada metode ini, KIRI akan mengambil data secara berkala dari angkot.web.id, sehingga akan terdapat jeda antara perubahan data dan terbaharuinya data KIRI.

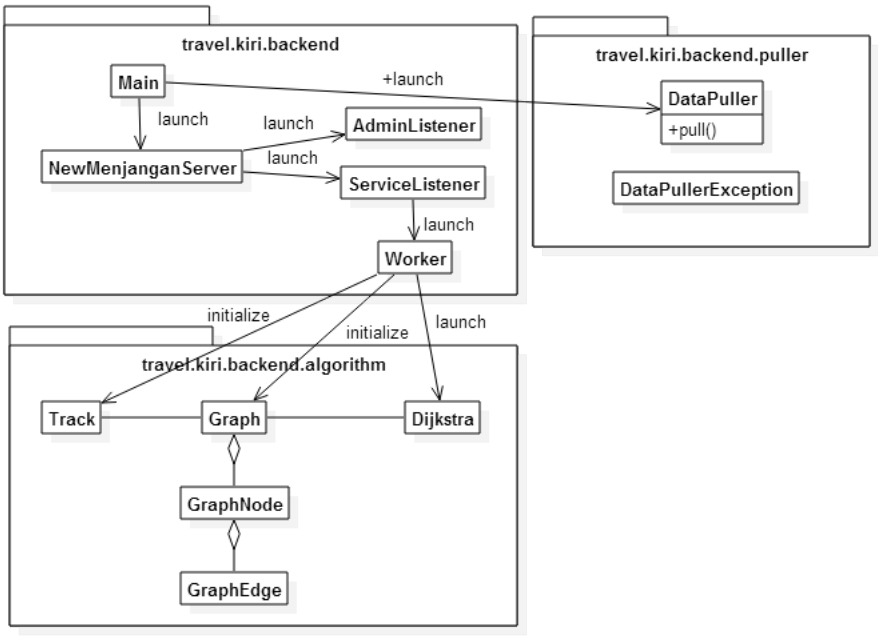
Dari kedua metode tersebut, peneliti memilih untuk menggunakan metode *polling* dengan alasan-alasan sebagai berikut:

Lebih sedikit perubahan Angkot.web.id menggunakan protokol HTTP yang bersifat *conectionless*, sehingga secara alami akan menunggu perintah dari *client*, alih-alih secara aktif memberi notifikasi kepada *client*. Jika menggunakan metode *polling*, KIRI dapat memanfaatkan protokol *Transportation Detail* yang sudah dimiliki oleh angkot.web.id.

Mengurangi kebutuhan prosesor Rute pada KIRI dimodelkan dalam bentuk graf, dan sebelum dapat digunakan untuk pencarian graf ini harus dikonstruksi terlebih dahulu. Akibat besarnya data yang digunakan, konstruksi ini akan memakan waktu (kurang lebih 30 detik). Dengan menggunakan metode *realtime*, setiap perubahan data pada kiri.web.id akan mengakibatkan graf ini harus direkonstruksi ulang. Dengan menggunakan metode *polling*, penarikan data dan rekonstruksi graf dapat diatur sedemikian sehingga dilakukan pada saat pengguna sedang tidak aktif.

Urgensi Perbaikan Data Peneliti berpendapat bahwa urgensi perbaikan data tidak terlalu tinggi untuk KIRI (bandingkan dengan perubahan harga saham, *realtime GPS monitoring*, dll).

Penulis menetapkan penggunaan metode *polling* selama 24 jam sekali, dan dipilih waktu 0.30 (setengah jam setelah tengah malam) untuk melakukan *polling*. Penetapan waktu ini mempertimbangkan sedikitnya penggunaan KIRI pada saat tengah malam. Jeda setengah jam dilakukan



Gambar 3.1: Diagram Kelas Sistem Usulan (Tahap Analisis)

untuk memberikan toleransi terhadap perbedaan waktu komputer beberapa detik, yang mungkin memberikan masalah pada tanggal sistem.

3.1.2 Penyimpanan Data

Penyimpanan data diusahakan untuk meminimalisir perubahan serta menjaga kompatibilitas dengan versi sebelumnya. Seperti yang telah dibahas pada bab 2, mesin navigasi KIRI menggunakan berkas `tracks.conf` sebagai jembatan dari basis data menuju mesin navigasi. Berkas inilah yang akan dikonstruksi menjadi graf oleh kelas `Worker`. Peneliti memutuskan untuk tidak mengubah format dari berkas ini, melainkan melakukan modifikasi pada basis data.

Pada basis data, tetap diusahakan untuk meminimalisir perubahan. Dari struktur tabel `tracks` yang digunakan, diidentifikasi bahwa kolom 'internalInfo' tidak digunakan dalam perhitungan (tidak berpengaruh pada konstruksi graf). Oleh sebab itu, kolom ini menjadi kandidat untuk disisipkan informasi terkait dengan penarikan data dari angkot.web.id. Adapun informasi yang harus disimpan adalah:

- Penanda bahwa rute ini ditarik dari angkot.web.id
- Kode yang mengacu pada basis data angkot.web.id, dalam hal ini `id`.

3.1.3 Analisis Aplikasi

Pada penelitian ini, mesin navigasi KIRI dimodifikasi dengan menambahkan dua kelas baru, yaitu kelas `DataPuller` yang difungsikan sebagai penarik data dari angkot.web.id, serta kelas `DataPullerException` untuk mencatat kesalahan pada saat menarik data dari angkot.web.id. Kelas-kelas yang baru serta yang lama digambarkan pada diagram kelas di gambar 3.1.

3.2 Angkot.web.id

Pada dasarnya angkot.web.id tidak diperlukan adanya perubahan, karena KIRI dapat memanfaatkan protokol *transportartion detail*. Namun, untuk keperluan optimasi, ada sedikit perubahan yang dijelaskan pada subbab berikutnya.

3.3 Optimasi

Dengan mekanisme yang sudah dijelaskan di subbab sebelumnya, data pada KIRI dapat tersinkronisasi dengan angkot.web.id. Namun, mekanisme tersebut dirasa tidak optimal. Setiap pukul 0.30, KIRI akan menarik ke-33 rute angkot yang dicatat pada angkot.web.id, terlepas dari apakah ada perubahan pada rute angkot atau tidak. Walaupun hanya menarik 33 rute dan dilakukan pada jam tidak sibuk, peneliti merasa optimasi tetap dibutuhkan sehingga solusi ini skalabel.

Mekanisme *Transportation List* maupun *Transportation Detail* pada angkot.web.id memberikan informasi *updated* yang menunjukkan waktu terakhir rute ini diperbaharui. Pada saat menarik data dari angkot.web.id, informasi ini dapat dicatat dan disimpan pada basis data, untuk dibandingkan pada kesempatan berikutnya. Jika informasi *updated* yang terdapat pada basis data sama atau lebih baru dibandingan dengan yang didapat dari angkot.web.id, maka tidak diperlukan adanya penarikan rute dari angkot.web.id. Adapun informasi yang dicatat pada basis data KIRI menjadi sebagai berikut:

- Penanda bahwa rute ini ditarik dari angkot.web.id
- Kode yang mengacu pada basis data angkot.web.id, dalam hal ini `id`.
- **Waktu terakhir rute ini berubah pada angkot.web.id**

Perlu dicatat pula bahwa tidak semua data trayek di angkot.web.id akan diintegrasikan dengan KIRI. Oleh karena itu, dibutuhkan sedikit perubahan pada angkot.web.id, sehingga KIRI dapat menarik informasi untuk rute-rute yang dibutuhkan saja. Detail dari perubahan ini akan dijelaskan pada bab berikutnya.

BAB 4

PERANCANGAN

4.1 Perancangan Aplikasi Mesin Navigasi KIRI

Seperti telah dibahas pada bab analisis, ada beberapa penambahan kelas pada mesin navigasi KIRI. Adapun kelas utama yang ditambahkan adalah kelas `DataPuller` yang bertanggung jawab untuk menarik data dari angkot.web.id. Kelas ini memiliki beberapa *method* antara lain:

- **public void (File sqlPropertiesFile, PrintStream output)**
  Berfungsi untuk memeriksa seluruh trayek di basis data. Untuk trayek yang memenuhi syarat (terintegrasi dengan angkot.web.id dan terdapat data yang lebih baru di angkot.web.id), melakukan penarikan.
  Parameter:
  - **sqlPropertiesFile** menunjukkan berkas yang menyimpan konfigurasi dari basis data yang akan digunakan.
  - **output** tempat di mana hasil dari penarikan akan ditulis (pada umumnya akan ditulis ke berkas tracks.conf).

  Kembalian: tidak ada.

- **private static LngLatAlt[] lineStringToLngLatArray(String wktText)**
  Method bantuan untuk mengubah teks dari format *Well-known text* [**?**] menjadi *array latitude* dan *longitude*. Hal ini diperlukan karena MySQL mengembalikan data rute dalam format *Well-known text* tersebut, sedangkan pemrosesan dalam bahasa Java lebih mudah jika datanya memiliki struktur.
  Parameter:
  - **wktText** Teks yang berisi data rute dalam format *Well-known text*

  Kembalian: rute dalam *array latitude* dan *longitude*

- **private static double computeDistance(LngLatAlt p1, LngLatAlt p2)**
  Method bantuan untuk menghitung jarak dari dua buah titik dalam format *latitude* dan *longitude*. Perhitungannya menggunakan metode *haversine*[1]. **Parameter:**
  - **p1** titik pertama

[1] http://www.movable-type.co.uk/scripts/latlong.html

  - **p2** titik kedua

  Kembalian: jarak kedua titik tersebut dalam kilometer

- **private RouteResult formatTrack(String trackTypeId, String trackId, LngLatAlt[] geodata, boolean isPathLoop, String penalty, String transferNodesStr, int lastUpdate))**
  Mengkonversikan sebuah data trayek dalam format yang digunakan pada berkas tracks.conf. **Parameter:**

  - **trackTypeId** kode tipe trayek
  - **trackId** kode trayek angkot
  - **geodata** titik kedua
  - **isPathLoop** titik kedua
  - **penalty** titik kedua
  - **transferNodeStr** titik kedua
  - **lastUpdate** titik kedua

  Kembalian: informasi rute dalam format berkas tracks.conf

- **private RouteResult formatTrackFromAngkotWebId(String angkotId, String trackTypeId, String trackId)**
  Mengkonversikan data dari situs angkot.web.id menjadi format yang digunakan pada berkas tracks.conf. **Parameter:**

  - **angkotId** kode angkot pada angkot.web.id
  - **trackTypeId** kode tipe trayek
  - **trackId** kode trayek angkot

  Kembalian: informasi rute dalam format berkas tracks.conf

Selain itu, peneliti juga membuat kelas lain `RouteResult` yang merupakan *inner class* dari `DataPuller`, untuk menampung hasil dari pembuatan rute serta pembacaan rute dari angkot.web.id. Kelas ini memiliki beberapa atribut antara lain:

- int **lastUpdate**
  Menyimpan tanggal terakhir rute ini diperbaharui di angkot.web.id dalam format UNIX time.

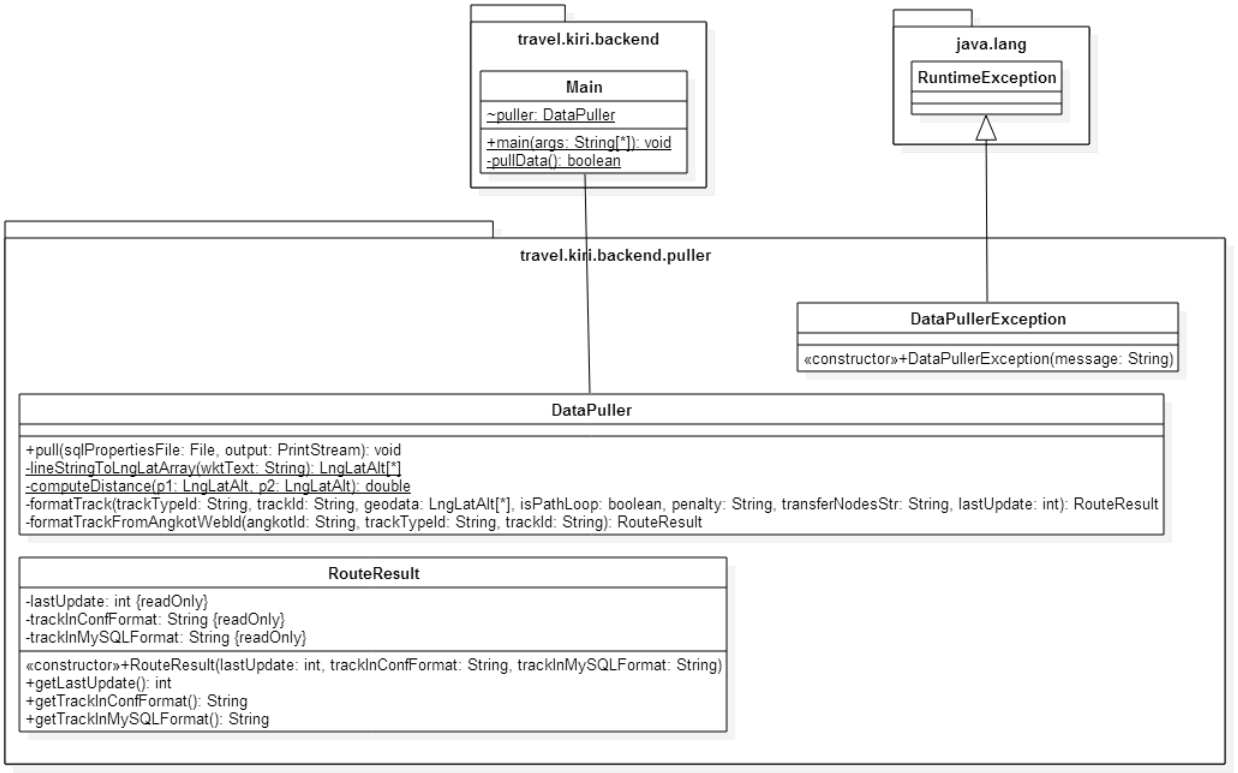
- String **trackInConfFormat**
  Menyimpan representasi rute ini dalam format berkas tracks.conf.

- String **trackInMySQLFormat**
  Menyimpan representasi rute ini dalam format query MySQL.

Kelas `RouteResult` tidak memiliki method kecuali konstruktor dan getter.

Terakhir, ditambahkan pula kelas `DataPullerException` untuk mencatat segala eksepsi pada saat menarik data dari angkot.web.id.

Detail seluruh kelas yang ditambahkan dapat dilihat pada kelas diagram pada gambar 4.1.



Gambar 4.1: Diagram Kelas (Tahap Desain)

4.2 Perancangan Protokol

Protokol untuk melakukan sinkronisasi dibuat di atas protokol *Transportation List* dan *Transportation Detail* milik situs angkot.web.id. Di awal sinkronisasi, mesin navigasi KIRI mencatat trayek apa saja yang harus disinkronkan dengan angkot.web.id. Kemudian, mesin navigasi KIRI akan mengirimkan permintaan *Transportartion List* dengan menyertakan parameter id/kode angkot angkot.web.id, yang dipisahkan dengan *pipe* ("|"). Tambahan parameter ini merupakan hasil dari optimasi protokol yang sudah ada, sehingga jawaban yang dikirimkan hanya mencakup angkot yang diperlukan oleh KIRI saja.

Contohnya, permintaan *Transportation List* yang meminta status dari angkot dengan kode 1 dan 2 saja menggunakan perintah `GET /route/transportation-list.json?id=1|2`. Hasil dari permintaan tersebut akan menghasilkan kembalian kurang lebih seperti berikut:

```
{
   "transportations":[
      {
         "city":"Jakarta",
         "id":1,
         "updated":"1381097188",
         "number":"M17",
         "province":"ID-JK",
         "company":"Mikrolet",
         "created":"1376493332",
         "destination":"Pasar Lenteng Agung",
         "origin":"Pasar Minggu",
         "hasRoute":true
      },
      {
         "city":"Jakarta",
         "id":2,
         "updated":"1379737743",
         "number":"S616",
```

```
20            "province":"ID-JK",
21            "company":"Kopaja",
22            "created":"1376494541",
23            "destination":"Cipedak",
24            "origin":"Blok M",
25            "hasRoute":true
26        }
27    ],
28    "status":"ok",
29    "provinces":[
30        [
31            "ID-AC",
32            "Aceh"
33        ],
34        ...
35     ]
36 }
```

Dari kembalian di atas, mesin navigasi KIRI dapat mengetahui kapan rute di angkot.web.id terakhir diperbaharui, untuk trayek-trayek yang diminta. Untuk setiap rute yang telah berubah, KIRI mengirimkan lagi perintah berikutnya, yaitu *Transportation Detail*, yang memberikan rute penuh untuk trayek yang diminta. Sebagai contoh, jika rute dengan kode 1 ditemukan telah berubah, maka akan dikirimkan perintah *Transportation Detail* `GET /route/transportation/1.json`. Dari situ, rute lengkap akan disimpan pada berkas `tracks.conf`.

4.3 Perancangan Antarmuka

4.3.1 Antarmuka Mesin Navigasi KIRI

Mesin navigasi KIRI adalah program yang dijalankan sebagai server, sehingga hanya memiliki antarmuka minimal berbasis teks yang menampilkan aksi-aksi yang dilakukan oleh server. Setelah ditambahkan fitur menarik data dari angkot.web.id, maka akan ada tambahan penampilan aksi menarik rute seperti contoh berikut (tambahan ada pada baris 1-8):

```
1  May 20, 2015 1:56:02 PM travel.kiri.backend.puller.DataPuller pull
2  INFO: Fetching https://angkot.web.id/route/transportation-list.json?id=157|247|636...

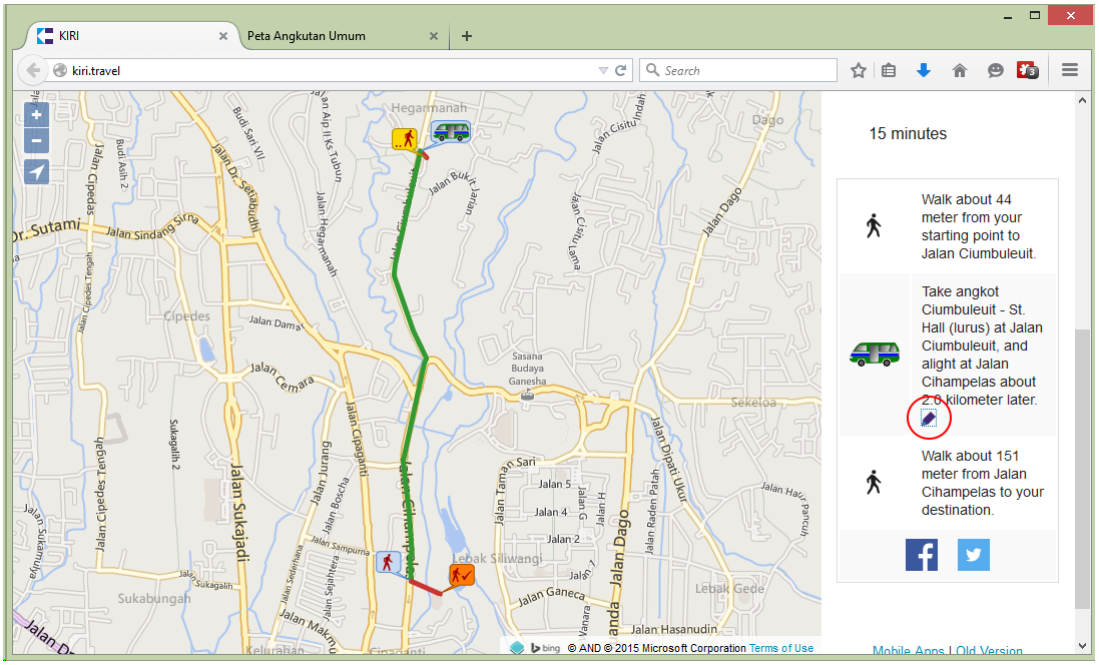
```

4.3.2 Antarmuka Situs Web KIRI

Pada situs web KIRI, jika ditemukan rute yang dihasilkan terintegrasi dengan angkot.web.id, maka situs akan menambahkan sebuah tombol kecil berbentuk pensil, yang jika diklik akan membawa pengguna ke situs angkot.web.id untuk memodifikasi rute terkait. Tampilan tombol tersebut dapat dilihat di 4.2.



Gambar 4.2: Tombol ubah di situs web KIRI

BAB 5

INTRODUCTION

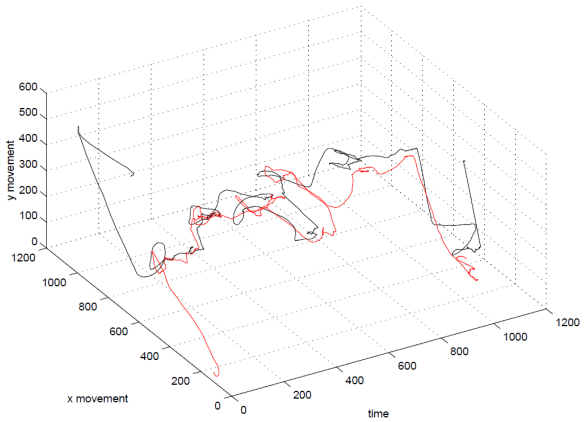
5.1 Motivation

A trajectory is the motion path of a moving object. Various moving objects such as animals (probably in a wildlife area), hurricanes, or customers in a shopping area have trajectories that can provide valuable information. For example, trajectory data can be used to predict the movement of the same type of object in similar situation in the future.

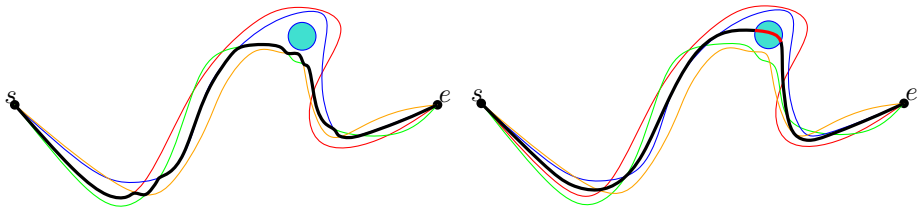
During a tracking procedure, the location of these moving objects can be obtained using various location detection devices (e.g: RFID, GPS devices and mobile phones). Later, this information will be sent to a database using any communication network (usually a wireless network). Because typical trajectory data is obtained during a specific interval, then trajectory data also has a temporal component, besides its spatial component.

The trajectory of a moving object is typically modeled as a sequence of consecutive locations in a multi-dimensional (generally two or three dimensional) Euclidean space [1]. Figure **??** shows an example of two trajectories from two objects which are moving in a 2D plane. With their temporal component, we can see that these trajectories are represented as polylines in a 3D space.

Nowadays, with the rapid development of technologies in mobile computing and wireless communication, many devices with location acquisition capabilities make it possible to obtain huge volumes of trajectory data from various moving objects. Furthermore, analysis of trajectory data is an important task for many applications that contain processing and managing moving objects,



Gambar 5.1: Example of 2D trajectories with time component, from [1]



Gambar 5.2: Example of the median (left) and the mean (right) trajectory [2]

such as animal movements [8, 9, 10, 11], traffic and transport analysis [12], defense and surveillance areas [13], oceanographic observations[1], weather and natural phenomena [14], people behavior [15] and sports [16, 17].

Previous work on trajectory data analysis shows that there are several ways to analyze sets of trajectories. For example, similarity between trajectories can be determined [18, 19, 20]. Trajectories can also be clustered into groups with similar characteristics [21, 22, 23, 24]. Other examples are common data mining tasks such as classification [25, 26] and outlier detection [27]. Furthermore, interesting movement patterns such as flocking can also be computed from a set of trajectories [28, 29, 30, 31].

Even though analysis and research on trajectories has expanded in recent years, several basic concepts still need to be studied further. Some of them are the median and the mean trajectory for a collection/set of trajectories. The median and the mean trajectory share some common properties: they should be similar to other trajectories in the set and all parts of them should be located roughly in the middle of the set. However, there are several important differences between them: Firstly, the median trajectory must use only parts of trajectories in the set. It uses only parts of one trajectory or combines parts from many different trajectories. This property might be a disadvantage for the median because some parts of it can be located not in the middle of the set, but in several situations this might be useful.

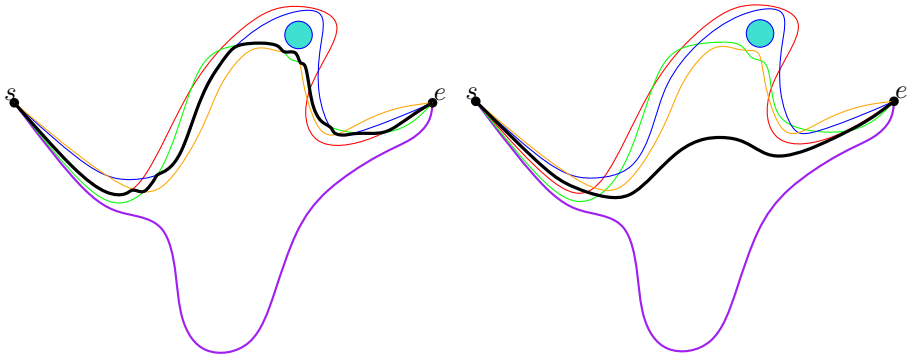
Figure **??** shows a set of four trajectories which avoid the light-blue obstacle. The possible mean trajectory (the black trajectory in the right-hand side of the figure) will pass through the obstacle because the mean must lie in the middle of all trajectories in the set. In this case, it is clear that the mean trajectory is not suitable for a path of a moving object.

The median trajectory (black trajectory in the left-hand side of the figure) gives a more suitable path because it always uses parts of other trajectories. In parts near the obstacle, the median is not really in the middle of other trajectories.

Secondly, the median trajectory is more robust against outliers than the mean trajectory. Figure **??** shows this situation: we add one trajectory (with purple color) which can be categorized as an outlier compared to other trajectories. While the median trajectory only needs to be modified a little bit, the mean trajectory has to be changed a lot (comparing to the mean trajectory in Figure **??**), to keep it in the middle of other trajectories.

In this thesis, we will not cover the mean trajectory and only discuss the median trajectory and algorithms to compute it. We also ignore the temporal component of the trajectory because it is not clear yet how to take it into account when computing the median trajectory. However, some

[1] W.S. Kessler, "Argo work in the coral sea."http://faculty.washington.edu/kessler/noumea/gliders/argo_coral_sea.html, March 2010.



Gambar 5.3: Robustness of the median trajectory

research on motion and kinetic data structures contains a temporal component and are related to the median/mean trajectory [32, 33].

For other types of data, a median has a clear definition. The median from a population (or a sample) of integer numbers is the number that separates the population into two halves, where at most half of the population have a smaller value and the other half of the population have a larger value than the median.

For geometric data types, the concept of median also exist. A *center point* of a set P of n points in the plane is a point such that any closed half-plane whose bounding line contains the center point, contains at least $n/3$ points of P [34]. If we force the center point to be one of the points from P, then we obtain a 2-dimensional version of the median, although the "quality" of this median can be bad.

The median trajectory does not have any formal definition yet. Based on several properties that we mention earlier, such as its similarity with other trajectories and lying approximately in the middle of the set, we can determine a possible median, which can useful in several ways:

5.1.1 Determine the most typical trajectory

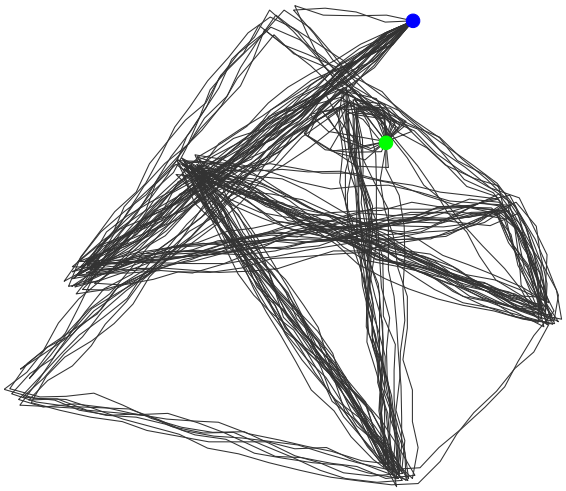
The property of the median trajectory makes it suitable to analyze the movement behavior or movement pattern from a group of same objects because the median somehow represents the whole trajectories in the set/collection. The median trajectory properties, such as the length, the direction or the average speed (if we include the temporal component), could give valuable information.

Example applications include the detection of outliers, which can be done by analyzing the length and the similarity of the shape of the median with other trajectories. Analyzing the average speed together with the shape of the median trajectory might be useful to understand the behavior and the movement pattern of people walking around in an area which has several interesting places to be visited (e.g., a zoo or an amusement park).

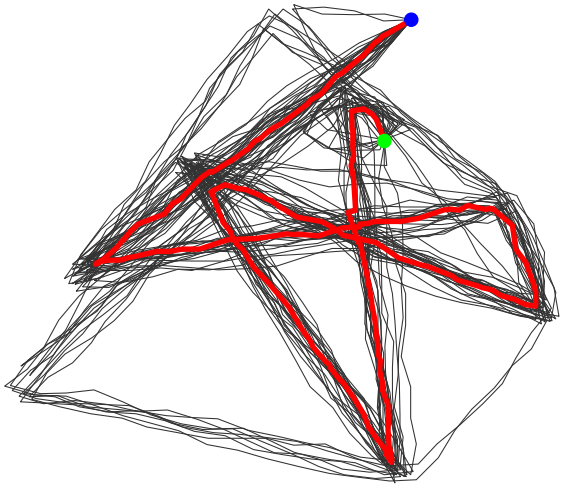
5.1.2 Better visualization for a set of trajectories

Visualization of the median trajectory, together with its set of trajectories, might give the viewer a better interpretation and information about the set of trajectories.

We give an example in Figure **??**, where a set has 30 trajectories, which is paths of 30 objects moving from the blue point to the green point. From this figure, we can hardly tell anything



Gambar 5.4: The set of 30 trajectories,starting at the blue point & ending at the green point



Gambar 5.5: A set of 30 trajectories with its possible median trajectory

about the general behavior or the direction of these trajectories. However, we know that several trajectories are different than others and probably can predict what the majority does, but it is still difficult to visualize what the majority of these trajectories does.

In the following figure (Figure **??**), we present a possible median trajectory as the red and thick trajectory. From this visualization, it is clear what the majority of trajectories does. Moreover, we can identify what parts of some trajectories are completely different from others.

The visualization of the median trajectory could be useful in some real-life applications: The median trajectory from trajectories of visitors in a national park can be used to see the most common path taken by visitors, which is probably the path that is preferred by future visitors. This information might be useful if we want to create a map that can help those visitors by providing valuable information about a path and direction on that national park in the map, so that he/she can decide which path that he/she will take.

5.1.3 k-medoid clustering

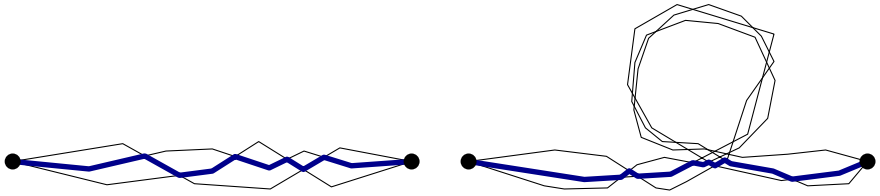
Another application that could use the median trajectory is the k-medoid algorithm, which is used in cluster analysis. The k-medoid clustering algorithm is related to the k-means algorithm, a method to partition/group a set of objects into k different clusters containing similar objects.

In general, each cluster in both algorithms has one object act as a *central object* and other members of the cluster should be similar or having a small distance to this object. The similarity or the distance between objects can be measured using different distance functions (e.g. Euclidean distance, Minkowski distance, etc), depending on the type of objects and the purpose of the clustering.

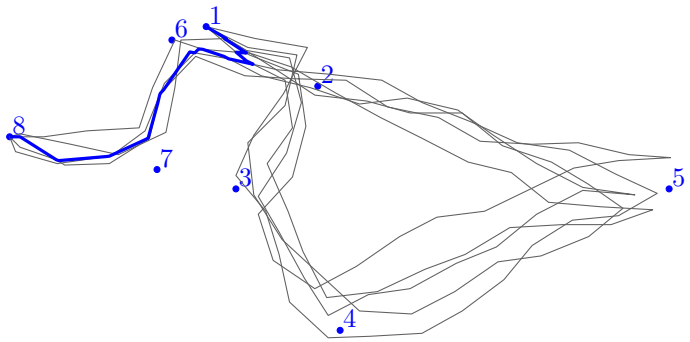
The main difference between the two algorithms is on the selection of the central object for each cluster. While the k-means simply uses the mean of objects, the k-medoid must use the medoid (an object which has the smallest average of dissimilarity/distance to all other objects in the set, but it must be a member of the set). This implies that k-means could create a new object to be the central object whereas the k-medoid must use one of the objects from the set. Thus, the k-medoid algorithm is more suitable for spatial clustering purposes and less sensitive against noise and outliers.

Partitioning Around Medoids (PAM) [35] is a basic k-medoid clustering algorithm. It works as follow:

1. Define a value k and choose k objects as a set of medoids.
2. Assign every object to its closest/similar medoid and after that, compute the cost for the whole configuration.
3. Find another configuration by selecting a pair of medoid and non-medoid objects which have the smallest distance cost and swapping them temporarily. Then, we assign all other objects to this temporary set of medoids and obtain a new configuration.
4. If the new configuration has smaller cost than the last configuration, then we change the set of medoids and return to step 3
5. Otherwise, stop and we find the set of medoids with their non-overlapping set of clusters.



Gambar 5.6: Illustration of the simple idea using switching



Gambar 5.7: The median trajectory makes a shortcut [2]

In case we want to cluster a set of trajectories, we can use the median trajectory as a medoid in this algorithm. However, some changes probably should be made. For example, finding another configuration is not done by simply swapping the median with other trajectory, instead we can choose to swap part of them (with the requirement that both trajectories intersect one another).

5.2 Basic Idea of the Research

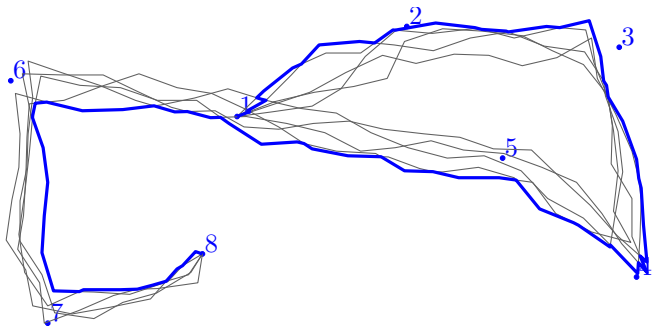
Consider a set T of m trajectories. We want to to compute the median trajectory of T. In this set, all trajectories have the same start and end points. The median trajectory of T must be built using parts of trajectories in T and somehow must follow what other trajectories in T do, while staying in the "middle" of other trajectories.

5.2.1 The Simple Switching Method

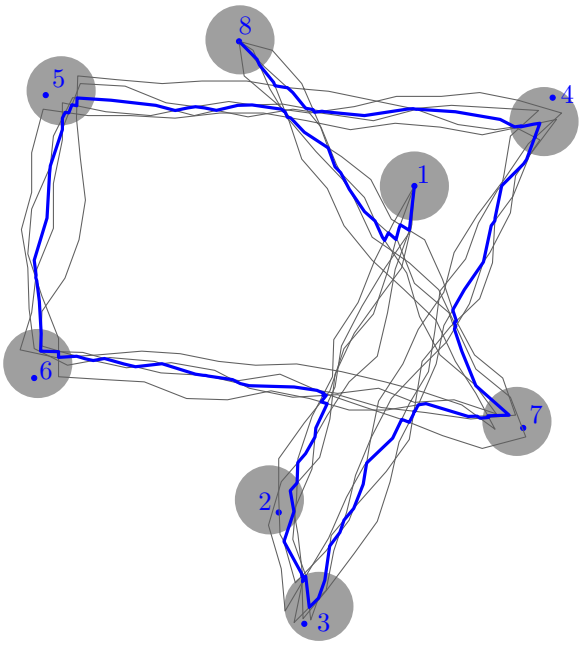
A simple idea to obtain a median trajectory from T is to start from the "middle" trajectory, which is the $(m+1)/2$-level of arrangement formed by all trajectories in T (we assume m is odd). At every intersection point, the median trajectory will switch to another trajectory and keep $(m+1)/2$ trajectories above and below the median [36].

Figure **??** shows the result (the median trajectory is the thick-blue trajectory) of this approach for two different types of set of trajectories, one of them contains trajectories with self intersection. From the right-hand side of the figure in Figure **??**, we can see that this method cannot produce suitable median trajectory because the median does not follow the loop created by the three trajectories.

In general, this method will not give a suitable median if a set of trajectories contains self-intersecting trajectories. More examples from [2] show several "incorrect" median trajectories obtained by using this simple switching method. The blue median trajectory in Figure **??** makes a



Gambar 5.8: The median trajectory does not stay in the middle [2]



Gambar 5.9: The median trajectory does not follow the correct sequence of regions [2]

shortcut path to the end point.

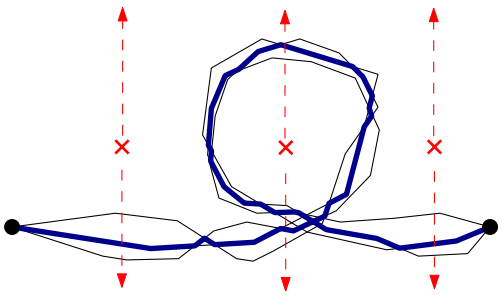
The median trajectory in Figure **??** does not stay in the "middle" of other trajectories. Finally, in Figure **??**, the median trajectory does not follow the sequence of regions as the other trajectories. The correct sequence of regions is $1-2-3-4-5-6-7-8$.

5.2.2 The Algorithm Using the Concept of Homotopy

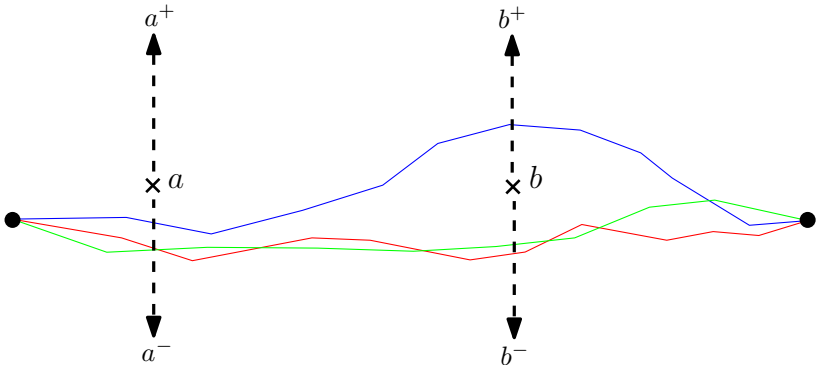
Another algorithm to compute the median trajectory uses the concept of homotopy (along with the modified simple switching method) [36]. This algorithm works by placing cross in a relatively large face bounded by segments from a set of trajectories. Figure **??** shows an example where cross is placed in the relatively large bounded face and two crosses are placed in the outer face.

Based on the location of these crosses, each trajectory in T will be assigned a *signature*. Figure **??** shows three trajectories and two crosses a and b. From these two crosses, four half-lines are created: a^+ and a^- are half-lines above and below a, while b^+ and b^- are half-lines above and below b, respectively.

For all trajectories in T, we give them a signature based on how they intersect with the half-



Gambar 5.10: Illustration of the algorithm using homotopy concept



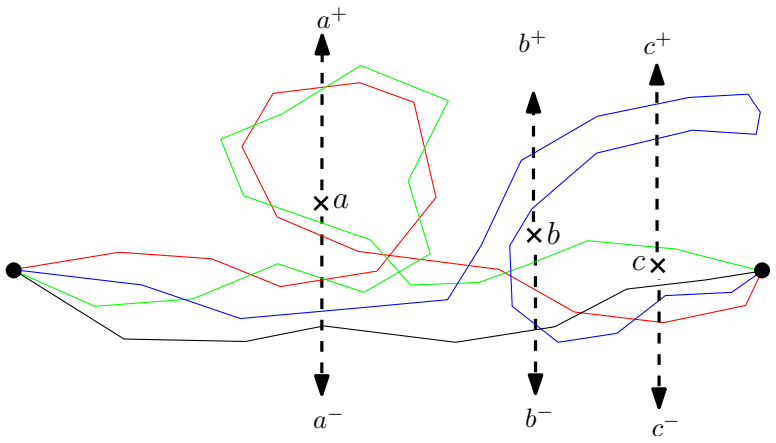
Gambar 5.11: Trajectories and crosses

line(s) from the crosses. Note that each trajectory might have a different signature, because it depends on the position of the trajectory with respect to all crosses in the plane. In Figure **??**, the blue trajectory intersect with a^- and b^+, thus its signature will be a^-b^+ (the order is following the direction of the trajectory). In the same way, the signature of the red trajectory will be the same as the green trajectory: a^-b^-.

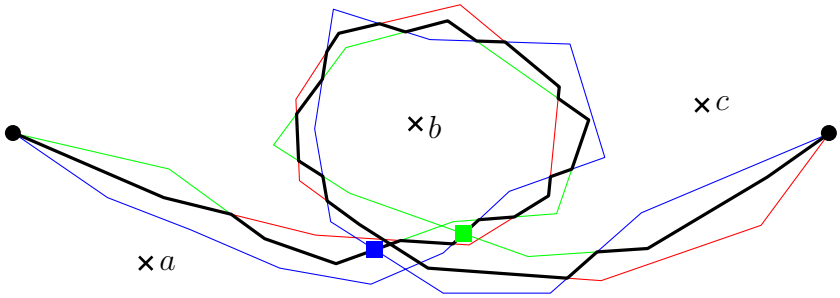
Two different trajectories are homotopic if one trajectory can be deformed continuously into the other one without passing through any crosses, while the start and end point are not moved. Naturally, two trajectories are homotopically equivalent if their signatures are exactly the same. However, two homotopic trajectories do not always have the same signatures. We shown an example in Figure **??** where the blue and the black trajectory are homotopic, but their signatures are different.

To determine whether two trajectories with different signature are homotopic or not, we perform a *reduce* operation. This *reduce* operation works by eliminating two exact same signs, if their position is next to each other in the signature. In Figure **??**, the signature of the blue trajectory is $a^-b^+c^+c^+b^+b^-c^-$. Notice that it has two c^+ that we can eliminate. This will change the signature of the blue trajectory into $a^-b^+b^+b^-c^-$. Once again, we can identify that two b^+ are positioned directly to each other. Performing the reduce operation again, we will get the final signature of the blue trajectory: $a^-b^-c^-$. At this point, we cannot apply the reduce operation again to this signature, and we say that the signature has been *maximally reduced*. Finally,we conclude that if two trajectories have the same maximally reduced signature, then the two trajectories are homotopically equivalent.

The next step of the algorithm is to create a subset T' of T, and then find the median trajectory by using only parts of trajectories from T'. Creating T' is straightforward, we only need to compute maximally reduced signature for all trajectories and choose a subset with the largest number of



Gambar 5.12: The blue and black trajectory are homotopically equivalent [2]



Gambar 5.13: Modified switching method [2]

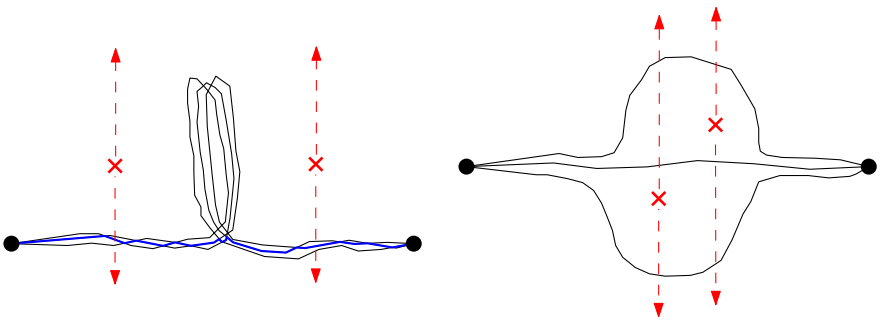
trajectories which have the same signature.

To create the median trajectory from T', we use the modified version of the switching method. This method start at the first segment of the"middle" trajectory. We find such a segment by determine the outer face of the set of trajectories. The first segment of the "middle" trajectory is the segment where there are $(n-1)/2$ first segments from other trajectories (assume n is odd) between the segment and the outer face (on each side of the segment).

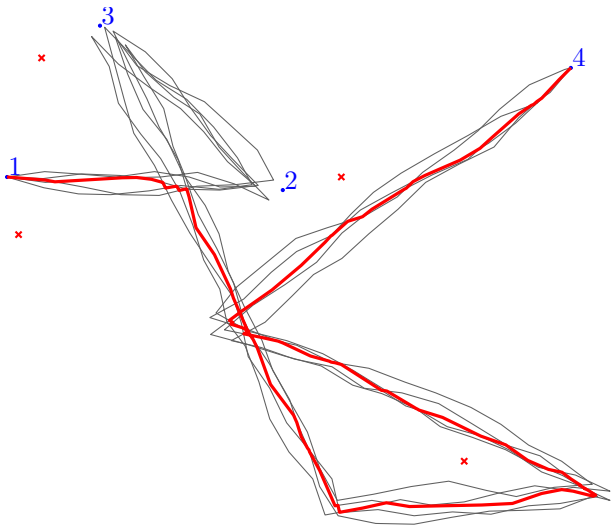
Then, at every intersection, the median will switch to another trajectory if the continuation along this trajectory (without ever switching again) gives the same signature with the signature of one trajectory from T'. Figure **??** shows an example of this algorithm. After starting with the red trajectory and switching to the green trajectory at the first intersection, the next intersection is with the blue trajectory (at the small blue square) and so far, the signature for the median is a^+. Although the blue trajectory is going forward, the signature after this intersection while following the blue trajectory (until the end point) is b^-c^-.

If the median switches at this intersection, the final signature will be $a^+b^-c^-$, which is not the signature of this set ($a^+b^-b^+b^-c^-$). At this point, the median does not switch to another trajectory. Instead, it continues to move along the green trajectory. The same situation also occurs when the median (now following the blue trajectory) intersects with the green trajectory (at the small green square).

Although this algorithm can produce a more suitable median trajectory for the situation where the switching method fails, the quality of the homotopic median trajectory depends heavily on the following factors:



Gambar 5.14: Example cases where algorithm using homotopy will fail



Gambar 5.15: The median trajectory does not pass through part of trajectories in the upper left area

- placement of the crosses
- the number of trajectories which have the same signature

Therefore, in several cases the algorithm with the homotopy concept cannot produce suitable median trajectories. We give two examples in Figure **??**: in the left-hand side of figure, the final median trajectory (blue) does not follow other trajectories to the area with a narrow space. This problem arises because that narrow space is not large enough for a cross to be placed.

In the right-hand side of the figure, there are no two trajectories homotopically equivalent to each other. Nevertheless, by looking at their position, the median trajectory should be the one in the middle (between the two crosses). However, the algorithm with the homotopy concept does not guarantee that a suitable median trajectory will be found because there is no subset that contains the majority of trajectories in T. Figure **??** shows an example from [2], where the median trajectory does not completely follow what other trajectories do.

5.2.3 The Proposed Solutions

To solve the problems we mention in the previous section, we propose two algorithms to compute the median trajectory from a set of m trajectories (where each trajectory has n segments).

The first algorithm is an $O(1.2108^m + m^5n^5)$ worst-case time algorithm. This algorithm uses the Fréchet Distance [37] and works similar to the algorithm using the homotopy concept because both of them have to create the largest subset of similar trajectories and then compute the median trajectory by using parts of trajectories in that subset. By using the Fréchet Distance, we avoid the requirement to find proper places to put crosses, but still can produce suitable median trajectory in the situation where the homotopic algorithm fails (e.g. the example with a narrow space).

The second algorithm uses the combination of the buffer concept and Dijkstra's Shortest Path algorithm. Unlike all previous algorithms, this algorithm does not need to find the largest subset consisting similar trajectories. Using this algorithm, we can compute the median trajectory in $O(h^2 \log h)$ time in the worst-case, where h is the number of all segments in T ($h = O(mn)$).

We implemented the second algorithm in Java programming language and experiments have been done to determine the quality of the resulting median trajectory produced by this algorithm. To provide the test data (set of trajectories), we use a trajectories generator instead of using real-world data. This allow us to test much larger sets of trajectories

5.3 Outline of the Thesis

Chapter 2 describes the properties for a set of trajectories and also some properties the median trajectory should have.

The next two chapters explain in detail the two algorithms:

- Chapter 3 starts with a brief introduction of the Fréchet Distance and after that, we will explain how to use it to compute the median trajectory.
- Chapter 4 introduces the method to compute the median trajectory using the combination of the buffer concept and Dijkstra's shortest path algorithm.

We will give an explanation about our implementation, particularly on the implementation of the trajectories generator, in Chapter 5. In Chapter 6, we present the measures used to evaluate the quality of the median trajectory, the experiments set-up and the results from the experiments. This thesis will be concluded in Chapter 7 and 8, where we draw conclusions and discuss some issues and possible directions for further research.

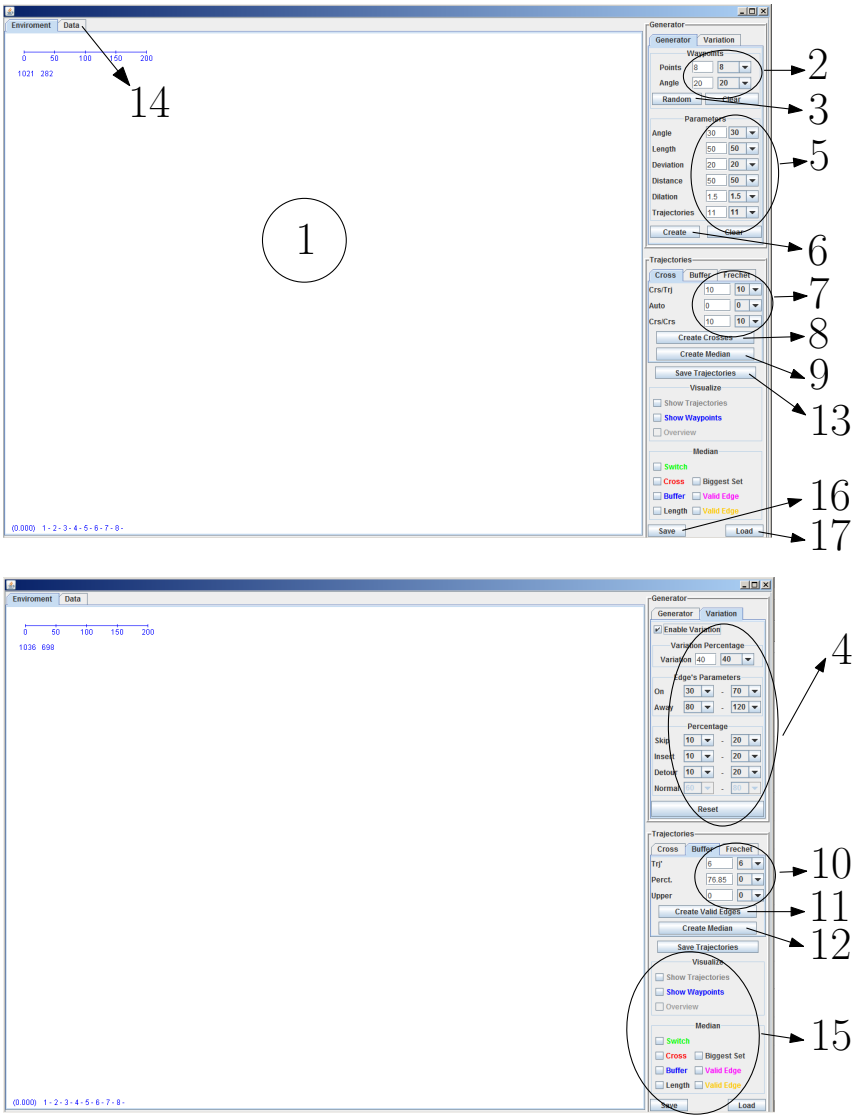
LAMPIRAN A

THE PROGRAM

The interface of the program is shown in Figure A.1:



Gambar A.1: Interface of the program

Step by step to compute the median trajectory using the program:

1. Create several waypoints. Click anywhere in the "Environment" area(1) or create them automatically by setting the parameters for waypoint(2) or clicking the button "Random"(3).

2. The "Variation" tab could be used to create variations by providing values needed to make them(4).

3. Create a set of trajectories by setting all parameters(5) and clicking the button "Create"(6).

4. Compute the median using the homotopic algorithm:

   - Define all parameters needed for the homotopic algorithm(7).
   - Create crosses by clicking the "Create Crosses" button(8).
   - Compute the median by clicking the "Compute Median" button(9).

5. Compute the median using the switching method and the buffer algorithm:

   - Define all parameters needed for the buffer algorithm(10).
   - Create valid edges by clicking the "Create Valid Edges"button(11).
   - Compute the median by clicking the "Compute Median"button(12).

6. Save the resulting median by clicking the "Save Trajectories" button(13). The result is saved in the computer memory and can be seen in "Data" tab(14)

7. The set of trajectories and its median trajectories will appear in the "Environment" area(1) and the user can change what to display by selecting various choices in "Visualize" and "Median" area(15).

8. To save all data to the disk, click the "Save"(16) button. A file dialog menu will appear.

9. To load data from the disk, click the "Load"(17) button.
